Dear think-cell Hiring Team,

I'm applying for the Senior Full Stack Developer — Web position. What drew me to this role is the scope of the problem: shaping a web platform that multiple teams depend on, making architectural calls that hold up over time, and working across both frontend and backend without being boxed into a narrow stack. That is exactly how I've worked for the past four years — and I do my best work in that kind of environment.

At **Lupply**, I built and operated an entire web platform ecosystem from scratch. Not just the user-facing sites (a SaaS dashboard, a food marketplace, an online store) but also the admin back-end, content management workflows, and the deployment pipelines that keep it all running. I was the sole engineer responsible for architectural decisions, performance optimization, and shipping across Web, iOS, Android, and Windows simultaneously. The admin dashboard I built lets non-technical team members manage products, orders, and content without touching code — which is the kind of CMS/publishing workflow challenge that maps directly to what you're building at think-cell.

One thing that caught my attention in the job description is the requirement to **interface with back-end systems written in C++**. Most web developers can't claim real experience with C++. I can. At NodeX iHub, I wrote C/C++ firmware running on ESP32 microcontrollers with FreeRTOS, built MQTT/TLS communication layers, and managed the entire hardware-to-cloud data pipeline. I understand memory management, system-level constraints, and the discipline that comes from working close to the metal. That background gives me a meaningful advantage when integrating web systems with C++ back-end services.

On the frontend side, my daily toolkit is HTML, CSS, JavaScript, TypeScript, React, and Next.js — with Tailwind CSS for styling (which I noticed is in your "nice to have" list). I care about Core Web Vitals, accessibility, and technical SEO because I've had to optimize for all three on platforms with real users and real traffic. At Lunar Finance, I worked on a high-traffic web platform serving 350k+ users where performance wasn't optional — it was the product.

Regarding PHP and Laravel specifically: I haven't worked with them in production. But I've picked up Go, Rust, Python, and multiple JavaScript frameworks on the job, shipping production code in each. Learning a new backend framework within an existing codebase is something I've done repeatedly, and I'd expect to be productive in Laravel quickly. What I bring is the engineering judgment to know *when* to build for flexibility and when to keep things simple — which matters more than any specific framework.

I am relocating to Berlin and hold verified documentation (Corporate Affairs Commission proof) of 4+ years of software engineering experience, which satisfies the requirements for the German IT Specialist Visa independently of a university degree. I could start within 3–4 months upon visa approval.

I'd welcome the chance to discuss how my platform-building experience, C++ systems background, and hands-on approach to web architecture could contribute to the think-cell web team.

Best regards,

Collins Krubu
